# *A novel method for analyzing grain facility heat treatment data*

## *~ Introduction ~*

---

- Management of Stored Product Insects (SPI) in grain processing facilities (chemical methods versus high temperatures)
- Heat treatment - a viable alternative to chemicals
- Target temperature  $\geq 50^{\circ}\text{C}$ , typically  $50^{\circ}$  to  $60^{\circ}\text{C}$
- Temp., duration of exposure, species, stages of development, RH determines insect survival.

*A novel method for analyzing grain facility heat treatment data  
~ Materials/Methods (1/2) ~*

---

- Pilot flour mill & cleaning house at KSU (6/99 & 8/99)
- Two heating systems: gas & electric
- Gas heating: heaters outside the building; hot air delivered inside the building through nylon ducts
- Electric heating: heaters within the building; power & monitoring cables running outside the building
- Fans used for uniform temperature distribution
- Time/temperature/RH recorded every 10 min at floor level; 16-22 data loggers per room.

*A novel method for analyzing grain facility heat treatment data*  
*~ Materials/Methods (2/2) ~*

---

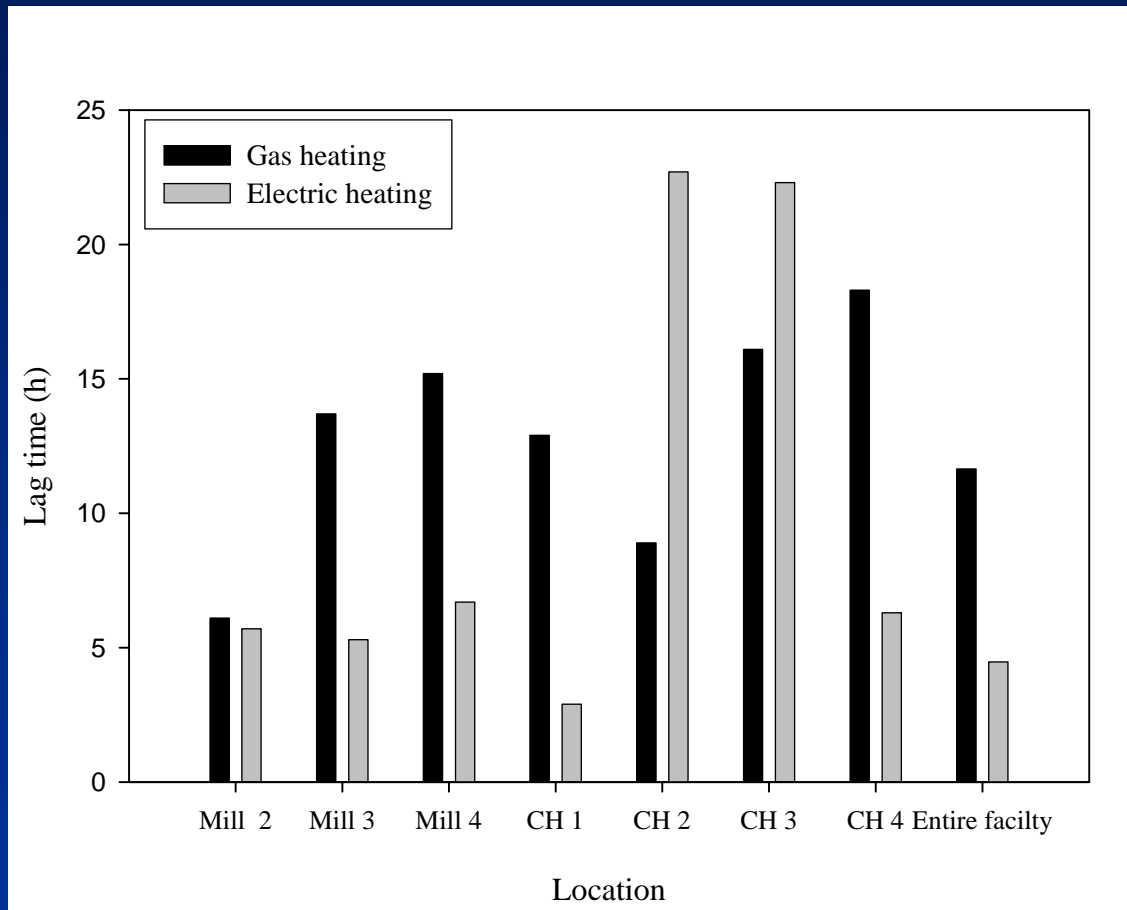

- Effectiveness of heat treatments compared by surface area method
- Surfer software used to calculate the surface areas
- % floor surface area  $< 50^{\circ}\text{C}$  as a function of time (duration of the heat treatment) and % floor surface area maximum floor temperature
- Contour maps of maximum floor temperature

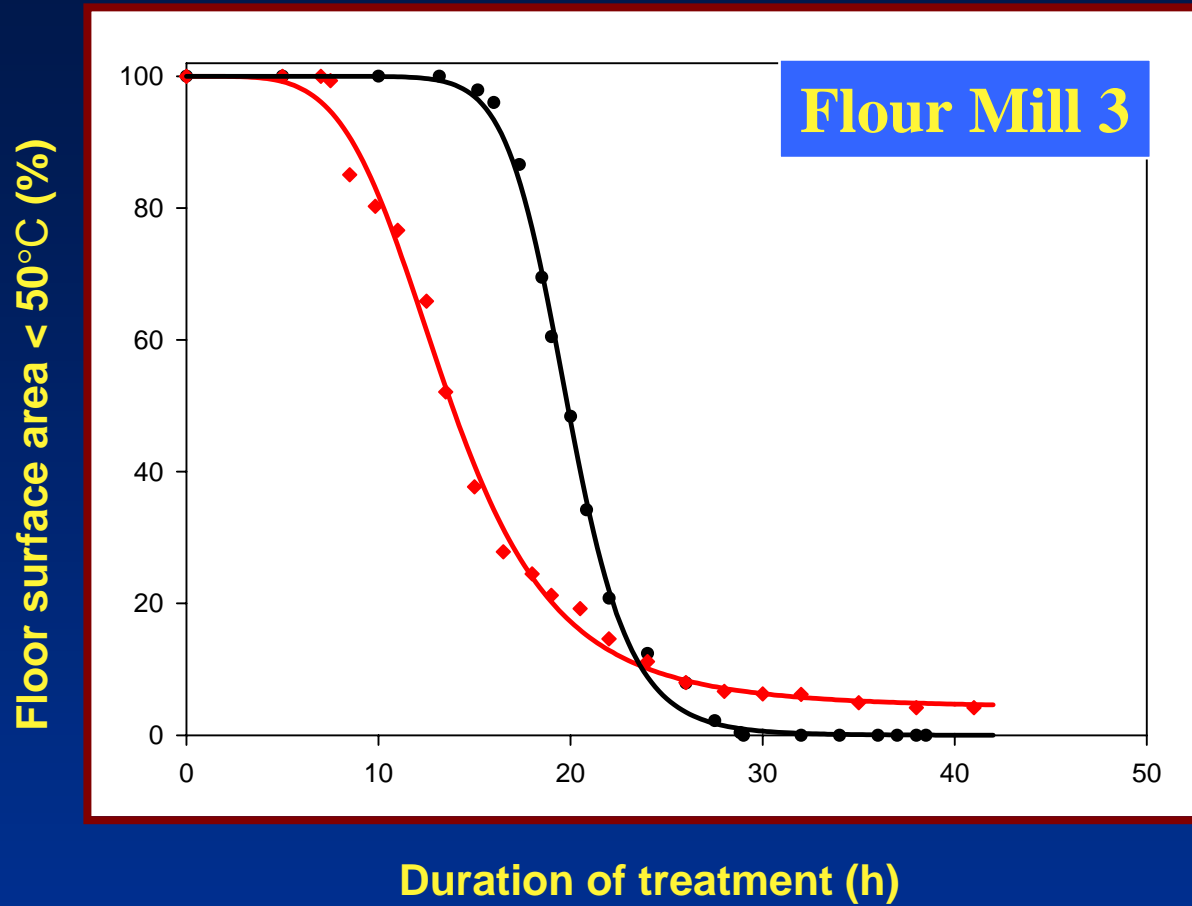

# A novel method for analyzing grain facility heat treatment data

## ~ Results ~

- Different heating patterns

### Lag times (time delays)

Red- electric heating  
Black- gas heating

# A novel method for analyzing grain facility heat treatment data

## ~ Results ~

### The surface area approach

- Surface areas calculated from *Surfer* outputs
- Normalized % surface area values for easy comparison

$$A_{norm} = \frac{A(t) - A_i}{A_f - A_i}$$

- ←  $A_{norm}$  is the nondimensional area under 50°C
- ←  $A(t)$  is the percent area < 50°C at time  $t$
- ←  $A_i$  is the % area < 50°C at the beginning of heat treatment
- ←  $A_f$  is the % area < 50°C at the end of heat treatment.

- Nonlinear regression - PROC NLIN procedure (SAS)

# A novel method for analyzing grain facility heat treatment data ~ Results ~

---

## The surface area approach (ctd.)

- A log-logistic equation used:

$$\text{Percent Surface Area} = \frac{1}{1 + e^{-b((\log_{10} \text{temperature}) - c)}}$$

- Pseudo-R<sup>2</sup> calculated. Ranged from 0.90-0.99.

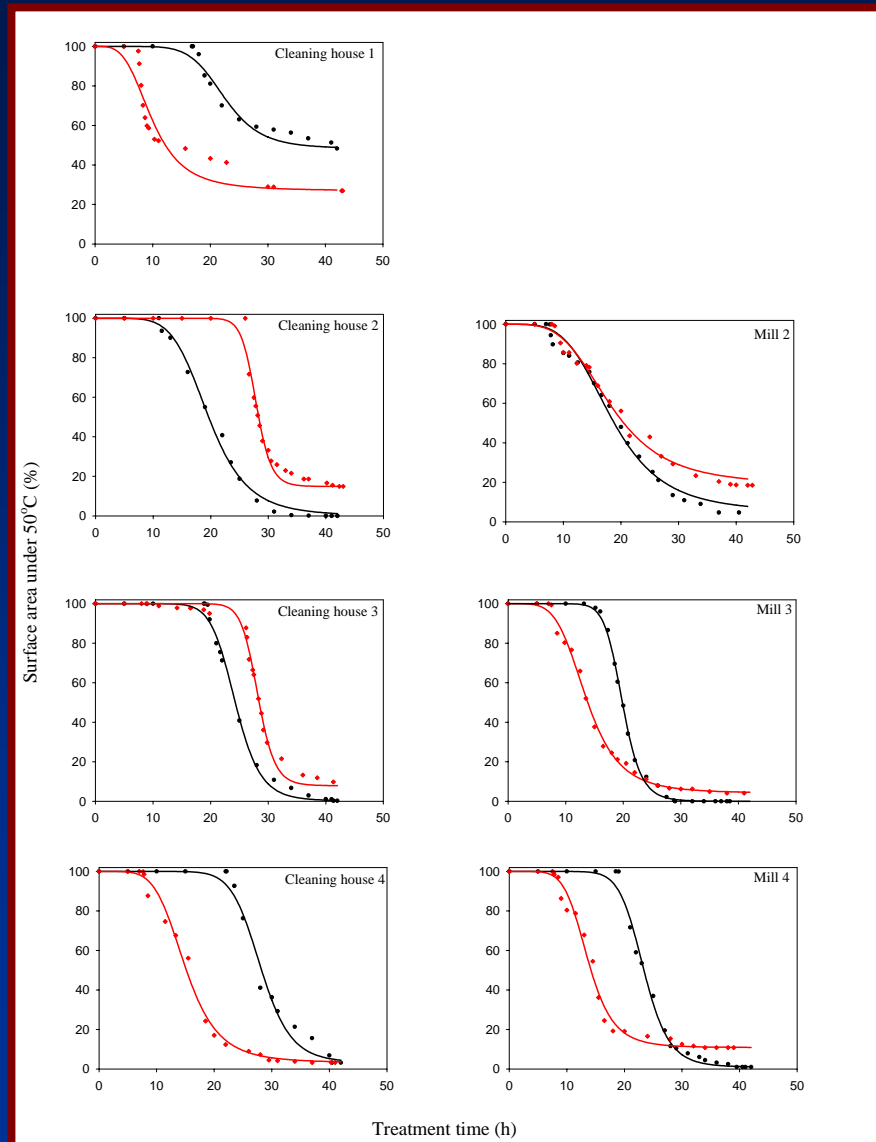

$$\text{Pseudo } R^2 = 1 - \left( \frac{SSR}{SST} \right)$$

SSR= Residuals Sum of Squares

SST=Total Sum of Squares

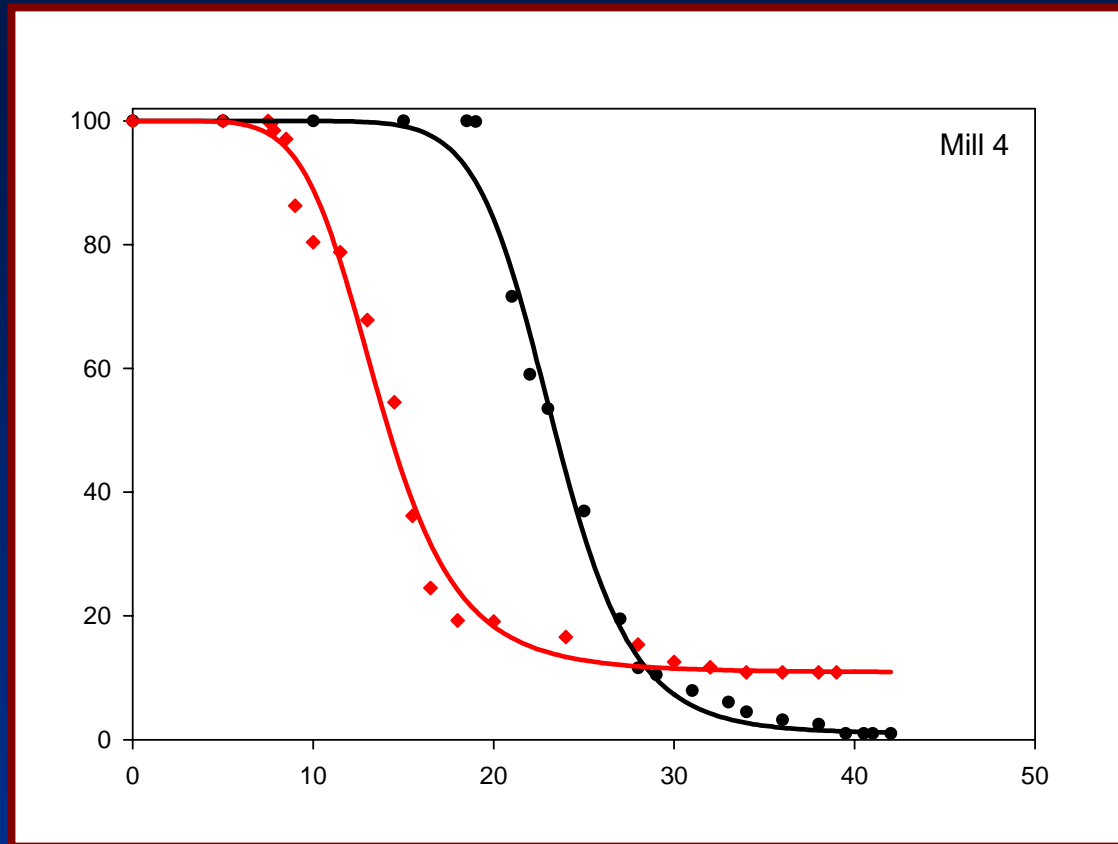

# Duration of treatment vs. % floor surface area < 50°C

# Flour Mill 4

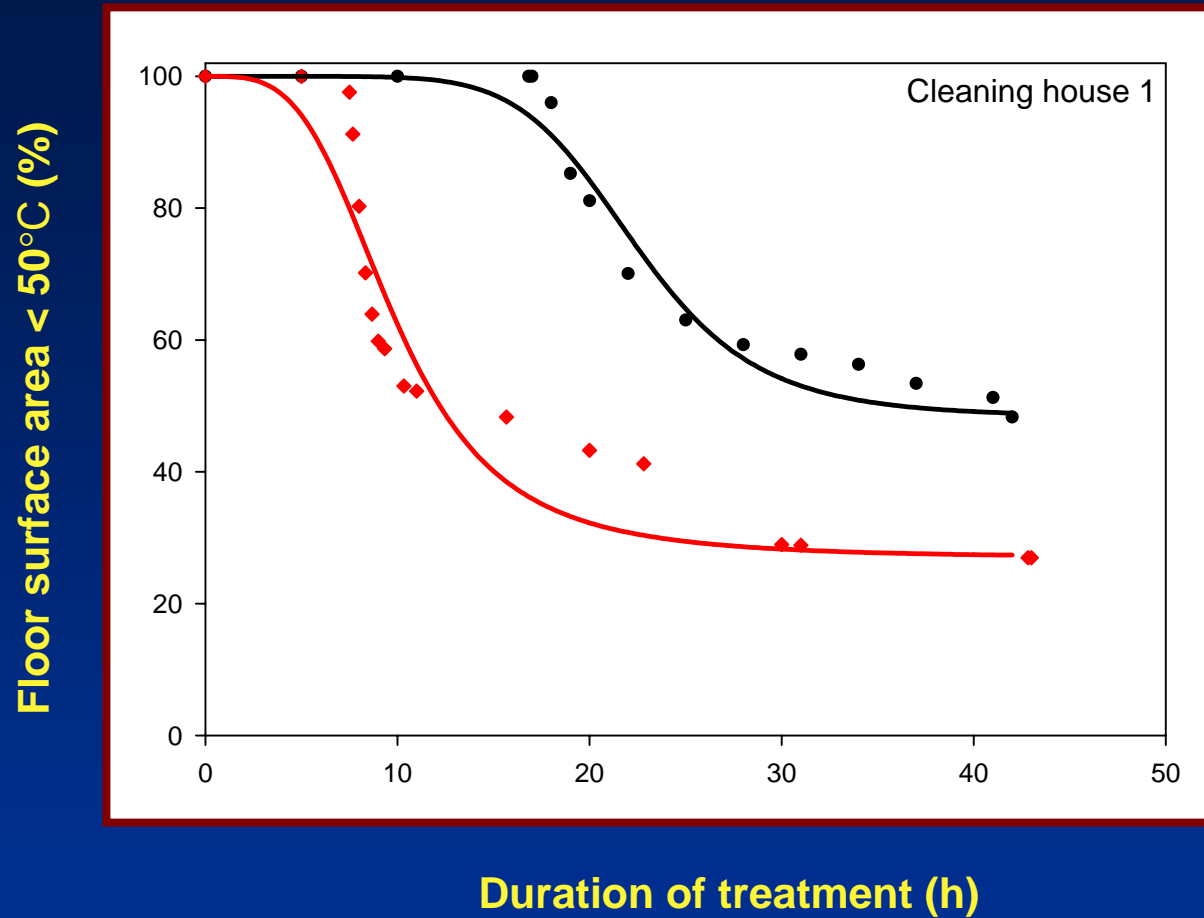

Floor surface area < 50°C (%)

Duration of treatment (h)

Black-gas heating

# Cleaning house 4

Red-electric heating  
Black-gas heating

# Max. floor temp. vs. % floor surface area

**red-electric heating**  
**black-gas heating**

# A novel method for analyzing grain facility heat treatment data

## ~ Results ~

---

- Time delays (lag times)
  - & Gas heating
    - † slower at the beginning
  - & Electric heating
    - † mostly shorter compared to gas heating
- Effectiveness of treatment ( $T < 50^{\circ}\text{C}$ )
  - & Gas heating
    - † less under-heated areas observed
  - & Electric heating
    - † more under-heated areas observed

# Electric heating

Cleaning house

Flour mill

## A novel method for analyzing grain facility heat treatment data ~ *Main points* ~

---

- Heat treatment as an alternative to chemical treatments
- Different heating patterns of gas and electric heating-Time delays; % A under/over-heated
- Sufficient heat treatment & uniform heat distribution
- Quantification & identification of over-heated & under-heated areas
- Characterizing the heating pattern of each method via modeling (log-logistic eqn.)

**Thank you**

**The End**
